Credit Card Approval Prediction System | Brainstorming & Ideation Phase

Persona: Priya, Credit Risk Analyst at a Regional Bank

Priya manually reviews 50+ credit card applications per day. She cross-references demographic data, income documents, and credit history to make approve/reject decisions, but the process is slow, inconsistent, and exhausting.

Quadrant	Details
SAYS	"I spend 15–20 minutes on each application just merging the data." "I wish I could get an instant risk signal before I start merging."
THINKS	"A tool that flags high-risk applicants would save hours every week." "The STATUS codes in credit history are confusing."
DOES	Pulls data from two separate systems (application DB + credit record DB). Manually checks STATUS codes in credit history to cross-reference.
FEELS	Overwhelmed by volume. Anxious about approving a high-risk applicant. Relieved when a tool gives a clear A or B recommendation.
PAINS	Two-table manual data merge is error-prone. No instant risk signal. Inconsistent decisions across analysts. A lot of rework.
GAINS	Instant Approved/Rejected decision from 17 features. Clear visual result page (green tick = Approved, red cross = Rejected).
